Abstract—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders between two groups of female nurses working in different departments of a tertiary care hospital. The prevalence of musculoskeletal disorders was determined by means of a self-administered questionnaire among 100 female nurses who worked in the intensive care unit (ICU) and 100 female nurses who worked in the medical-surgical department. The prevalence of musculoskeletal disorders was significantly higher in the ICU group than in the medical-surgical group ($p < .001$). The prevalence of musculoskeletal disorders was also significantly higher in the ICU group than in the medical-surgical group for each of the following variables: age, years of experience, type of shift, duration of workday, and frequency of lifting or carrying heavy objects.
